(accessible everywhere) and local (accessible only within a block/function.

Compilers represent scope using:-

i) Nested Symbol Tables:-
- Each block has its own symbol table.
- Tables are arranged in a hierarchical (tree-like) structure.
- Each table has a pointer to its parent (outer scope).

ii) Stack of Symbol Tables:-
- When entering a block → push new table.
- When exiting → pop table.
- Always search from top (current scope) to bottom.

Nested Blocks Example:-

```
{
   int x=10;
   {
      int y=20; //inner scope
      int x=30; //shadows outer x
   }
}
```

Outer Scope Table:-
x → int (value=10)

Inner Scope Table:-
y → int (value=20)
x → int (value=30) //shadows outer x

- Inside inner block: x=30 is used (local).
